

OS/161 Assignment 2 Report

Abu Bakar Siddique
Roll: 47

July 8, 2026

1 Implemented Work

- Implemented kernel synchronization primitives: locks and condition variables.
- Implemented process-related system calls: `fork`, `getpid`, `waitpid`, `_exit`, and `execv`.
- Added argument passing so user programs started from the kernel menu receive correct `argc/argv`.
- Implemented basic file system calls: `open`, `read`, `write`, `close`, and `remove`.
- Added file creation with `O_CREAT` and append behavior with `O_APPEND`.

2 Changed Files

- `kern/thread/synch.c`: lock and CV logic.
- `kern/include/proc.h`: PID and file handle structures.
- `kern/proc/proc.c`: PID table, wait support, file table setup/copy/cleanup.
- `kern/syscall/proc_syscalls.c`: process syscalls.
- `kern/syscall/file_syscalls.c`: file syscalls.
- `kern/arch/mips/syscall/syscall.c`: syscall dispatch.
- `kern/syscall/runprogram.c`: first-process argument passing.
- `kern/startup/menu.c`: forwards menu arguments.

3 Code Evidence and Explanation

3.1 System Call Interface

Syscall Prototypes

This screenshot shows the new kernel function declarations in `kern/include/syscall.h`. Functions such as `sys_fork`, `sys_waitpid`, `sys_open`, `sys_read`, and `sys_write` are declared here so the syscall dispatcher can call their implementations. This file acts like the common interface between the low-level trap handler and the syscall source files.

`screenshots/syscall-prototypes.png`

```
OS 161 Setup > Asst2 > source > os161-1.99 > kern > include > syscall.h

1  int sys_write(int fd, userptr_t ubuf, unsigned int nbytes, int *retval);
2  int sys_open(userptr_t filename, int flags, mode_t mode, int *retval);
3  int sys_close(int fd);
4  int sys_read(int fd, userptr_t ubuf, size_t buflen, int *retval);
5  int sys_remove(userptr_t pathname);
6  void sys__exit(int exitcode);
7  int sys_getpid(pid_t *retval);
8  int sys_waitpid(pid_t pid, userptr_t status, int options, pid_t *retval);
9  int sys_fork(struct trapframe *tf, pid_t *retval);
10 int sys_execv(userptr_t program, userptr_t args);

Created with SnippetShot
```

Syscall Dispatcher

The dispatcher reads the syscall number from the trapframe and uses a `switch` statement to call the correct kernel function. For example, `SYS_open` calls `sys_open`, `SYS_fork` calls `sys_fork`, and return values are placed back into the trapframe registers. This is the main entry point for user programs requesting kernel services.

screenshots/syscall-dispatcher.png

```
Setup > Asst2 > source > os161-1.99 > kern > arch > mips > syscall > sys

1  case SYS_write:
2      err = sys_write((int)tf->tf_a0,
3                      (userptr_t)tf->tf_a1,
4                      (int)tf->tf_a2,
5                      (int *)&retval);
6      break;
7  #if OPT_A2
8  case SYS_open:
9      err = sys_open((userptr_t)tf->tf_a0,
10                    (int)tf->tf_a1,
11                    (mode_t)tf->tf_a2,
12                    (int *)&retval);
13      break;
14  case SYS_close:
15      err = sys_close((int)tf->tf_a0);
16      break;
17  case SYS_read:
18      err = sys_read((int)tf->tf_a0,
19                    (userptr_t)tf->tf_a1,
20                    (size_t)tf->tf_a2,
21                    (int *)&retval);
22      break;
23  case SYS_remove:
24      err = sys_remove((userptr_t)tf->tf_a0);
25      break;

```

3.2 Synchronization

Lock Create

`lock_create` allocates memory for a lock, copies the lock name, creates the wait channel, initializes the internal spinlock, and sets the initial owner state to free. The wait channel is used when a thread must sleep, while the spinlock protects the lock's internal fields.

screenshots/lock_create.png

```
OS 161 Setup > Axt2 > source > os161-1.99 > kern > thread > synch.c

1 // Lock.
2 struct lock *
3 lock_create(const char *name)
4 {
5     struct lock *lock;
6
7     lock = kmalloc(sizeof(struct lock));
8     if (lock == NULL) {
9         return NULL;
10    }
11
12    lock->lk_name = kstrdup(name);
13    if (lock->lk_name == NULL) {
14        kfree(lock);
15        return NULL;
16    }
17
18    lock->lk_wchan = wchan_create(lock->lk_name);
19    if (lock->lk_wchan == NULL) {
20        kfree(lock->lk_name);
21        kfree(lock);
22        return NULL;
23    }
24
25    spinlock_init(&lock->lk_lock);
26    lock->lk_held = false;
27    lock->lk_holder = NULL;
28
29    return lock;
30 }
```

Created with Snippetshot

Lock Acquire and Release

lock_acquire first protects the lock state using the internal spinlock. If the lock is already held, the current thread sleeps on the wait channel until it is woken. **lock_release** clears the holder, marks the lock free, and wakes one sleeping thread so another thread can enter the critical section.

screenshots/lock_acquire+release.png

```
OS 161 Setup > Axt2 > source > os161-1.99 > kern > thread > synch.c

1 void
2 lock_acquire(struct lock *lock)
3 {
4     KASSERT(lock != NULL);
5     KASSERT(curthread->t_in_interrupt == false);
6     KASSERT(lock->lk_held == false);
7
8     spinlock_acquire(&lock->lk_lock);
9     while (lock->lk_held) {
10         wchan_lock(lock->lk_wchan);
11         spinlock_release(&lock->lk_lock);
12         wchan_sleep(lock->lk_wchan);
13         spinlock_acquire(&lock->lk_lock);
14     }
15     lock->lk_held = true;
16     lock->lk_holder = curthread;
17     spinlock_release(&lock->lk_lock);
18 }
19
20 void
21 lock_release(struct lock *lock)
22 {
23     KASSERT(lock != NULL);
24     KASSERT(lock->lk_held);
25
26     spinlock_acquire(&lock->lk_lock);
27     lock->lk_held = false;
28     lock->lk_holder = NULL;
29     wchan_wakeone(lock->lk_wchan);
30     spinlock_release(&lock->lk_lock);
31 }
```

Created with Snippetshot

Condition Variables

cv_wait is used when a thread cannot continue until some condition becomes true. It releases the caller's lock before sleeping and reacquires it after wakeup, preventing deadlock. **cv_signal** wakes one waiting thread, and **cv_broadcast** wakes all threads waiting on the condition variable.

screenshots/cv_wait+signal+broadcast.png

```

1 void
2 cv_destroy(struct cv *cv)
3 {
4     KASSERT(cv != NULL);
5
6     wchan_destroy(cv->cv_wchan);
7     kfree(cv->cv_name);
8     kfree(cv);
9 }
10
11 void
12 cv_wait(struct cv *cv, struct lock *lock)
13 {
14     KASSERT(cv != NULL);
15     KASSERT(lock != NULL);
16     KASSERT(lock_do_i_hold(lock));
17     KASSERT(curthread->it_in_interrupt == false);
18
19     wchan_lock(cv->cv_wchan);
20     lock_release(lock);
21     wchan_sleep(cv->cv_wchan);
22     lock_acquire(lock);
23 }
24
25 void
26 cv_signal(struct cv *cv, struct lock *lock)
27 {
28     KASSERT(cv != NULL);
29     KASSERT(lock != NULL);
30     KASSERT(lock_do_i_hold(lock));
31
32     wchan_wakeone(cv->cv_wchan);
33 }
34
35 void
36 cv_broadcast(struct cv *cv, struct lock *lock)
37 {
38     KASSERT(cv != NULL);
39     KASSERT(lock != NULL);
40     KASSERT(lock_do_i_hold(lock));
41
42     wchan_wakeall(cv->cv_wchan);
43 }

```

3.3 Process System Calls

getpid and waitpid

sys_getpid simply returns the PID stored in the current process structure. **sys_waitpid** validates that the requested PID belongs to a child process, sleeps until that child exits, then returns the encoded exit status to the parent through the user pointer. This gives the parent a controlled way to collect child termination information.

screenshots/sys-gerpid+waitpid.png

```

1 int
2 sys_getpid(pid_t *retval)
3 {
4     /*if (OPT_A2)
5     *retval = proc_getpid(curproc);
6     else
7     *retval = 1;
8     */
9     /*endif /* OPT_A2 */
10    return(0);
11 }
12
13 /* stub handler for waitpid() system call */
14
15 int
16 sys_waitpid(pid_t pid,
17             userptr_t status,
18             int options,
19             pid_t *retval)
20 {
21     int exitstatus;
22     int result;
23
24     if (options != 0) {
25         return(EINVAL);
26     }
27     /*if (OPT_A2)
28     if (status == NULL) {
29         return(EFAULT);
30     }
31     else
32     exitstatus = 0;
33     result = copyout((void *) &exitstatus, status, sizeof(int));
34     if (result) {
35         return(result);
36     }
37     result = proc_wait(pid, &exitstatus);
38     if (result) {
39         return(result);
40     }
41     else
42     exitstatus = 0;
43     */
44     /*endif /* OPT_A2 */
45     result = copyout((void *) &exitstatus, status, sizeof(int));
46     if (result) {
47         return(result);
48     }
49     *retval = pid;
50     return(0);
51 }

```

fork

sys_fork creates a new process by copying the parent's trapframe and address space. It also copies references to open file handles so the child inherits the parent's open files. After **thread_fork**, the parent returns the child PID, while the child enters user mode with return value 0.

screenshots/sys-fork.png

```

1 int
2 sys_fork(struct trapframe *tf, pid_t *retval)
3 {
4     struct fork_info *info;
5     struct proc *child;
6     int result;
7
8     info = kmalloc(sizeof(*info));
9     if (info == NULL) {
10         return ENOMEM;
11     }
12     info->tf = *tf;
13
14     result = as_copy(curproc->as, &info->as);
15     if (result) {
16         kfree(info);
17         return result;
18     }
19
20     child = proc_create_runprogram(curproc->name);
21     if (child == NULL) {
22         as_destroy(info->as);
23         kfree(info);
24         return ENOMEM;
25     }
26     proc_close_filetable(child);
27     result = proc_copy_filetable(child, curproc);
28     if (result) {
29         as_destroy(info->as);
30         proc_destroy(child);
31         kfree(info);
32         return result;
33     }
34     child->addressspace = info->as;
35
36     result = thread_fork(child->name, child, enter_forked_process,
37         info, 0);
38     if (result) {
39         child->addressspace = NULL;
40         as_destroy(info->as);
41         proc_destroy(child);
42         kfree(info);
43         return result;
44     }
45
46     *retval = proc_getpid(child);
47     return 0;
48 }

```

runprogram Arguments

`runprogram_args` loads the executable, creates the user address space, and copies argument strings onto the new user stack. It then builds the `argv` pointer array and passes `argc` and `argv` to `enter_new_process`. This is why menu commands with extra words can be received by user programs.

screenshots/run-program_args.png

```

1 int
2 runprogram_args(int nargs, char **args)
3 {
4     struct addressspace *as;
5     struct vnode *v;
6     vaddr_t entrypoint, stackptr;
7     userptr_t uargv;
8     int result;
9
10    ASSERT(nargs >= 1);
11
12    result = vfs_open(args[0], 0_RDONLY, 0, &v);
13    if (result) {
14        return result;
15    }
16
17    ASSERT(curproc->as == NULL);
18
19    as = as_create();
20    if (as == NULL) {
21        vfs_close(v);
22        return ENOMEM;
23    }
24
25    curproc->as = as;
26    as_activate();
27
28    result = load_elf(v, &entrypoint);
29    if (result) {
30        vfs_close(v);
31        return result;
32    }
33

35
36    result = as_define_stack(as, &stackptr);
37    if (result) {
38        return result;
39    }
40
41    result = runprogram_copy_args(nargs, args, &stackptr, &uargv);
42    if (result) {
43        return result;
44    }
45
46    enter_new_process(nargs, uargv, stackptr, entrypoint);
47    panic("enter_new_process returned 0");
48    return EINTR;
49 }

```

3.4 File System Calls

File Handle

The file handle structure stores the vnode, current offset, open flags, reference count, and a lock. The vnode points to the actual file object in the VFS layer. The offset tracks where the next read/write happens, and the refcount allows parent and child processes to safely share the same open file after `fork`.

screenshots/filehandle.png

OS 161 Setup > Asst2 > source > os161-1.99 > kern > include > p

```
1  #if OPT_A2
2  struct filehandle {
3      struct vnode *vn;
4      off_t offset;
5      int flags;
6      int refcount;
7      struct lock *lock;
8  };
```

Created with SnippetShot

Process File Table

Each process owns a file descriptor table named `p_filetable[OPEN_MAX]`. A user file descriptor is just an integer index into this table. When a file is opened, the kernel finds a free slot, stores the file handle there, and returns the slot number to the user program.

screenshots/filehandle2.png

OS 161 Setup > Asst2 > source > os161-1.99 > kern > include > proc.h

```
1  #if OPT_A2
2      pid_t p_pid;          /* Unique process id, 0 for kproc */
3      bool p_counted;      /* True after adding to proc_count */
4      struct filehandle *p_filetable[OPEN_MAX];
5  #endif /* OPT_A2 */
6  };
```

Created with SnippetShot

open and create

`sys_open` copies the filename from user memory using safe copy functions, checks the open flags, and calls `vfs_open`. After a `vnode` is returned, it creates a file handle and stores it in the process file table. `O_CREAT` is handled through the VFS open flags so a missing file can be created.

screenshots/sys-open.png

```

1  sys_open(const char *filename, int flags, mode_t mode, int *retval)
2  {
3      struct uio *ui;
4      struct iovec *iovec;
5      char *filename;
6      int fd;
7      int result;
8
9      if (filename == NULL) {
10         return EINVAL;
11     }
12     if (!flags_are_valid(flags)) {
13         return EINVAL;
14     }
15
16     fd = fd_alloc();
17     if (fd == 0) {
18         return ENFILE;
19     }
20
21     filename = malloc(PATH_MAX);
22     if (filename == NULL) {
23         return ENOMEM;
24     }
25     result = copystr((const char *)filename, filename, PATH_MAX, 0);
26     if (result) {
27         kfree(filename);
28         return result;
29     }
30
31     result = vfs_open(filename, flags, mode, 0);
32     if (result) {
33         return result;
34     }
35
36     fh = malloc(sizeof(*fh));
37     if (fh == NULL) {
38         vfs_close(fh);
39         return ENOMEM;
40     }
41     fh->lock = lock_create("open file");
42     if (fh->lock == NULL) {
43         vfs_close(fh);
44         return ENOMEM;
45     }
46     fh->vm = ui;
47     fh->offset = 0;
48     fh->flags = flags;
49     fh->refcount = 1;
50
51     uioopen->filetable[fd] = fh;
52     *retval = fd;
53     return 0;
54 }

```

read, write, and append

sys_read and **sys_write** use **uio** and **iovec** objects because OS/161 file I/O must safely transfer bytes between user memory and the kernel/VFS layer. The file handle lock protects the offset while I/O is happening. For **O_APPEND**, **sys_write** first moves the offset to the file size, then writes at the end.

screenshots/sys-read+write.png

```

1  int
2  sys_read(int fd, void *buf, int n, int *retval)
3  {
4      struct uio *ui;
5      struct iovec *iovec;
6      struct uio *ui;
7      struct iovec *iovec;
8      int fd;
9      int result;
10
11     if (fd == 0) {
12         return 0;
13     }
14     if (!fd_is_valid(fd)) {
15         return EINVAL;
16     }
17
18     fh = uioopen->filetable[fd];
19     lock_acquire(fh->lock);
20
21     if (fh->flags & O_APPEND) {
22         fh->offset = fh->vm->end;
23     }
24     if (fh->flags & O_RDONLY) {
25         if (fh->offset > fh->vm->end) {
26             result = 0;
27             goto out;
28         }
29     }
30     if (fh->flags & O_WRONLY) {
31         if (fh->offset > fh->vm->end) {
32             result = 0;
33             goto out;
34         }
35     }
36     if (fh->flags & O_RDWR) {
37         if (fh->offset > fh->vm->end) {
38             result = 0;
39             goto out;
40         }
41     }
42
43     result = ui_copy(fh->vm, buf, n);
44     if (result < 0) {
45         fh->offset = fh->vm->end;
46         result = 0;
47     }
48     lock_release(fh->lock);
49     return result;
50 }
51
52 int
53 sys_write(int fd, void *buf, int n, int *retval)
54 {
55     struct uio *ui;
56     struct iovec *iovec;
57     struct uio *ui;
58     struct iovec *iovec;
59     int fd;
60     int result;
61
62     if (fd == 0) {
63         return 0;
64     }
65     if (!fd_is_valid(fd)) {
66         return EINVAL;
67     }
68
69     fh = uioopen->filetable[fd];
70     lock_acquire(fh->lock);
71
72     if (fh->flags & O_APPEND) {
73         fh->offset = fh->vm->end;
74     }
75     if (fh->flags & O_RDONLY) {
76         if (fh->offset > fh->vm->end) {
77             result = 0;
78             goto out;
79         }
80     }

85         }
86     }
87     if (fh->flags & O_RDWR) {
88         if (fh->offset > fh->vm->end) {
89             result = 0;
90             goto out;
91         }
92     }
93
94     result = ui_copy(fh->vm, buf, n);
95     if (result < 0) {
96         fh->offset = fh->vm->end;
97         result = 0;
98     }
99     lock_release(fh->lock);
100    return result;
101 }

```

close and remove

sys_close clears the descriptor entry in the process file table and decreases the file handle reference count. When no process uses the handle anymore, the vnode is closed and memory is freed. **sys_remove** copies the pathname from user space and calls **vfs_remove** to delete the file from the mounted filesystem.

4 Test Commands

Build/run from Docker:

```
cd /root/cs350-os161
bash ./build-and-run-kernel.sh
```

Important OS/161 menu commands:

```
sy2
sy3
p /testbin/palin
p /testbin/argtest hello os161
mount sfs lhd0
p /testbin/filetest lhd0:testfile
```

5 Output Evidence and Meaning

5.1 Lock Test

Lock Test Output

The `sy2` test checks whether locks can be created, acquired, released, and destroyed without corrupting shared state. The final line `Lock test done.` means the lock implementation completed the test normally.

screenshots/asst2-02-sy2-lock.png

```

cpu0: MIPS r3000
OS/161 kernel [? for menu]: sy2
Starting lock test...
cleanitems: Destroying sems, locks, and cvs
Lock test done.
Operation took 0.315240160 seconds
OS/161 kernel [? for menu]:
[os161] 0:sys161*

```

5.2 Condition Variable Test

CV Test Output

The `sy3` test starts 32 threads and prints them in reverse order several times. This output means sleeping, waking, signaling, and broadcasting with condition variables are working. The final `CV test done` confirms the test finished.

5.3 User Program Execution

Palindrome Program Output

This screenshot shows that `/testbin/palin` runs in user mode. The program prints a long palindrome test and finishes with `IS a palindrome`, proving that user program loading and basic console output work.
